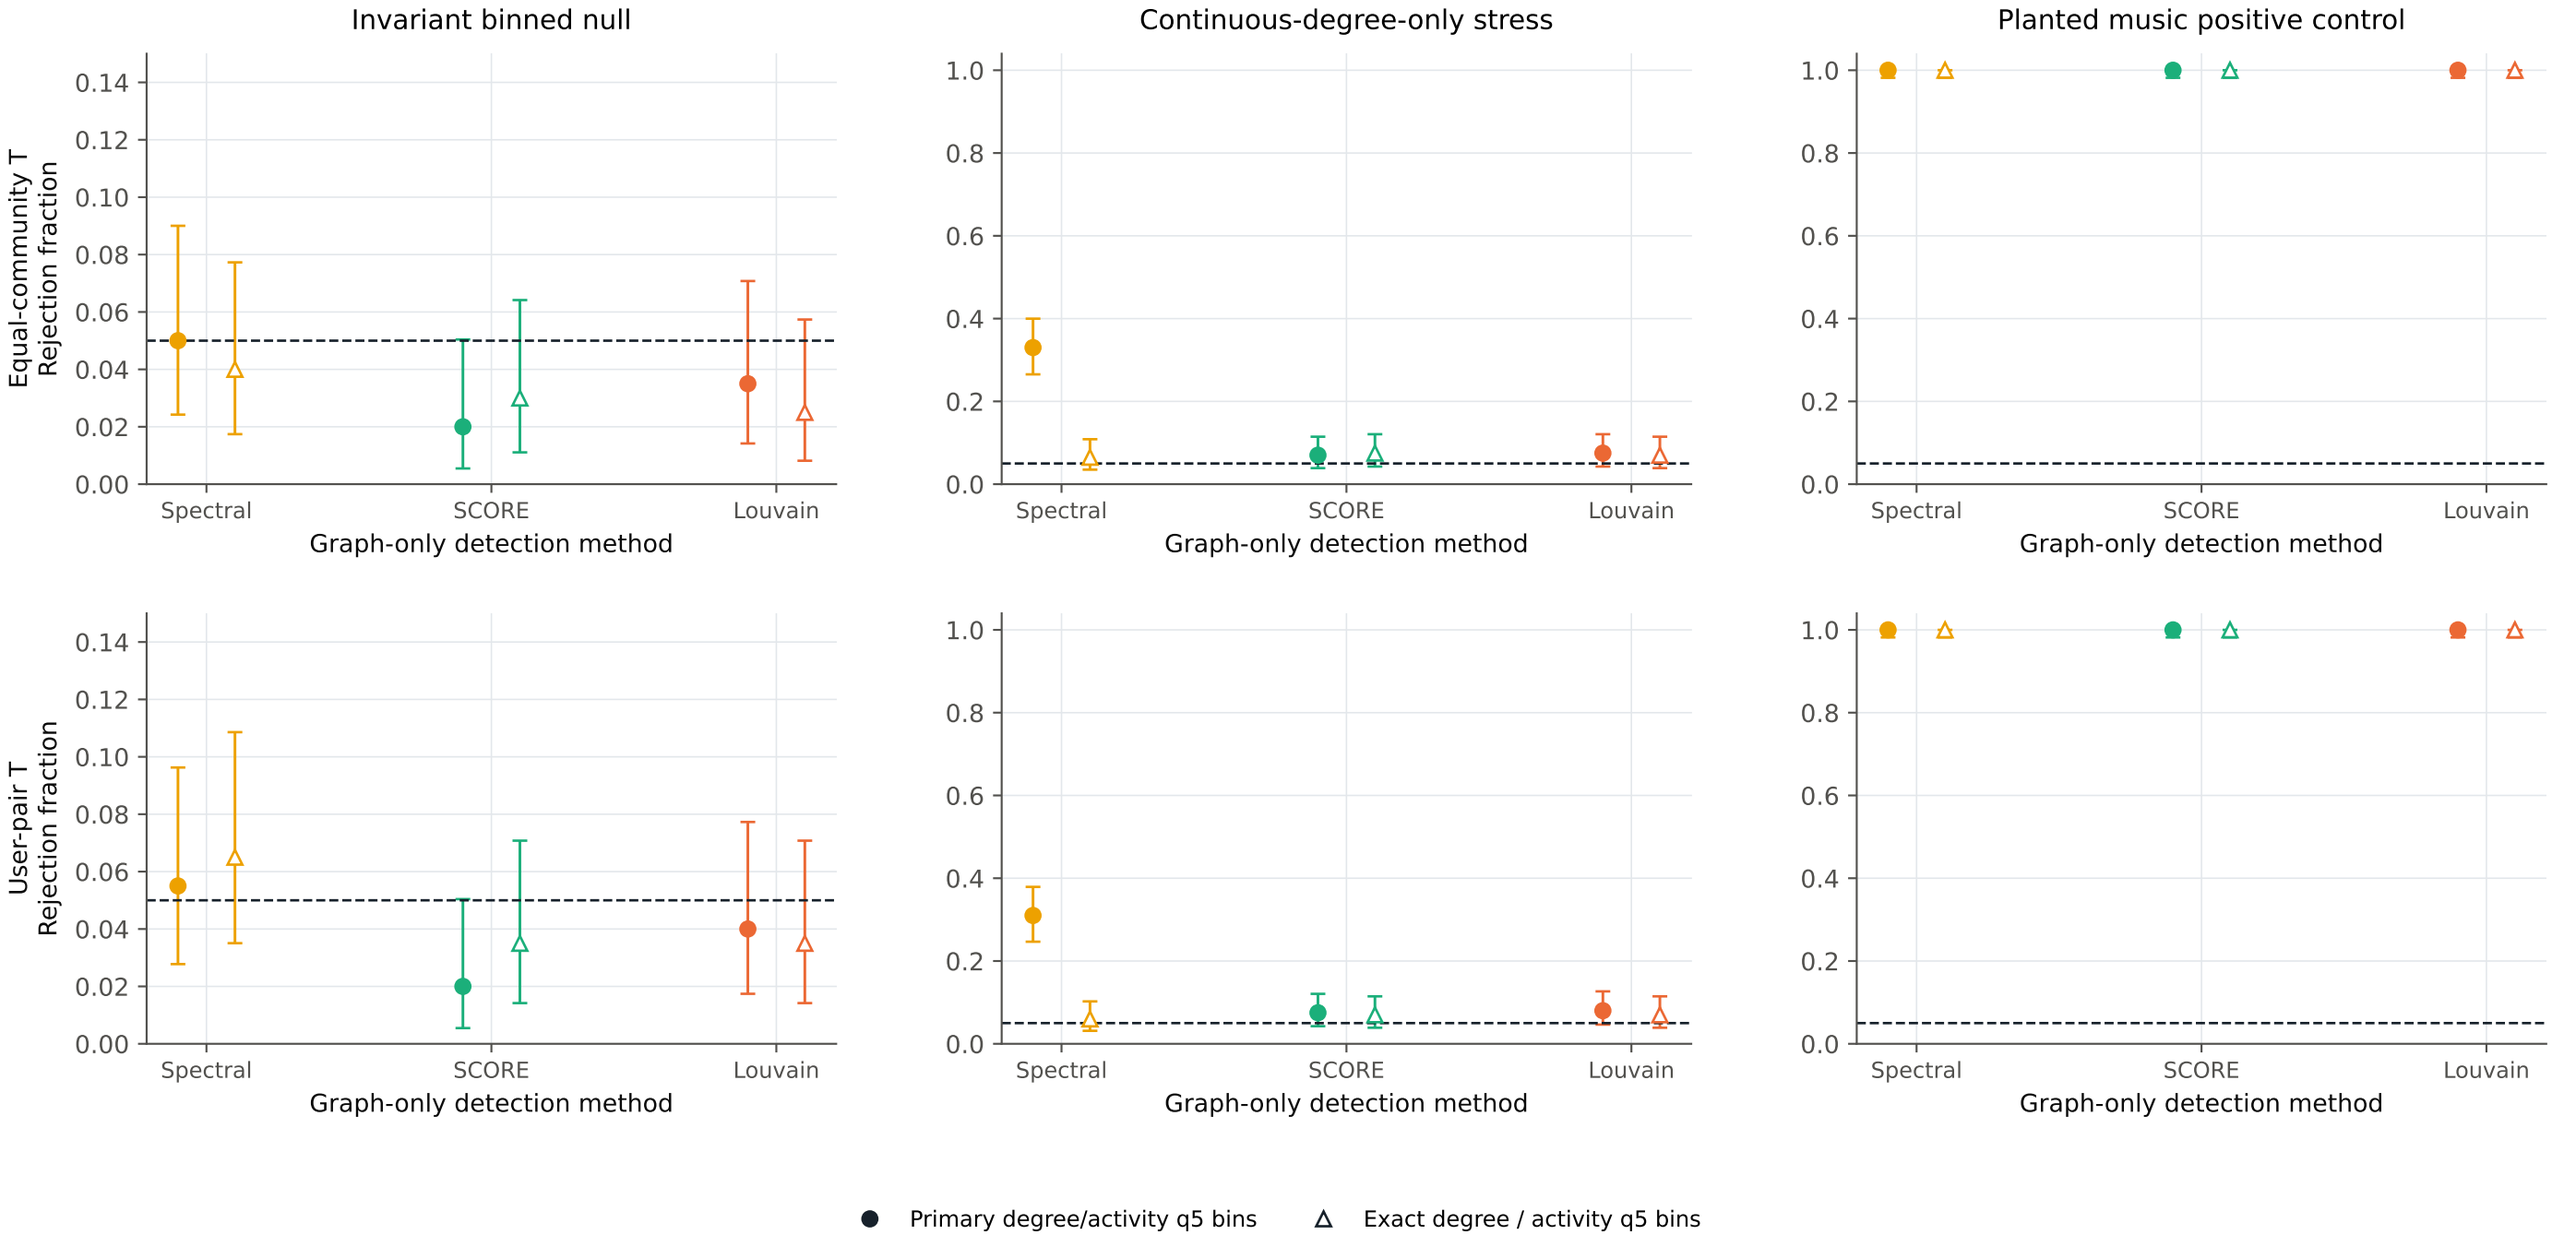
# Does the primary permutation procedure behave as intended?



200 independent music replications; 199 permutations each; bars: pointwise binomial Monte Carlo 95% intervals. Dashed line: alpha=.05.
Middle column: no community term beyond exact degree; q5 is approximate, so its rejection rate is a stress diagnostic, not exact-null size.
Left: both references are invariant nulls. Right: rejection measures power. These experiments do not establish exchangeability in LastFM.
